Summary of Report

Section 1200 of the Real Property Tax Law requires that the Department of Taxation and Finance monitor the equity of assessments in New York in the context of its periodic market value surveys, and report its findings to the Governor, the President Pro-Tem of the Senate, and the Speaker of the Assembly. The current report presents such an analysis, based on results from the 2012 survey.

Findings

Approximately 74 percent of the State's assessing units are indicated as having equitable assessment rolls. The number achieving overall equity had been rising steadily until the middle of the past decade (see Figure 1 in the report) and stands in dramatic contrast to the situation of about three decades ago when only about 10 percent had equitable assessments. However, in the latter half of past decade, equity levels retreated somewhat. It is believed that this reflects the influences of turbulent real estate markets in many areas, and the difficulty some assessors had in ensuring that their rolls reflect current market conditions. In the last two years, a modest upward trend in equity has reappeared, however.

A related positive trend has been the number of assessing units that have been updating their rolls on a frequent basis. As indicated in Figure 3 or the report, 427 units (43 percent) have submitted cyclical reassessment plans committing to a regular cycle of reappraisal. Although this is not a compulsory state requirement in New York, the State's reassessment aid program has been recently modified to encourage the use of a four-year updating cycle.

Despite the major progress that has occurred over the past few decades, much remains to be done. A significant number of assessing units, including many in rural regions of the State and some in its most populous areas such as the Lower Hudson Valley and Long Island, have not reassessed in many decades. Some small assessing units in rural areas of the State have difficulty finding the resources to perform the assessing function to today's standards, and need to explore consolidation and/or

coordination of effort in order to carry out their assessment duties equitably and efficiently.

In recent years, a "plateau" seems to have been reached in terms of local participation in existing state aid incentive programs for quality assessing. Thus, new methods of encouraging more communities to reassess have been sought, including the recent redesign of the reassessment aid program. This report also outlines a series of policy measures that are used in other states for the purpose of ensuring that local governments maintain current, equitable assessments, and recommends that they be considered in New York.

Methodology

The survey found that 552 assessing units (approximately 56 percent) implemented recent reassessment programs that could be used directly in determining 2012 municipal full value. For these assessing units, the survey process consisted of a review by Department staff of the reassessment roll and the procedures and data used to conduct the reassessment program. In cases where the assessed values appearing on the roll represented a recent year other than 2012, they were adjusted to the statewide value standard of July 1, 2011 that was used in the survey. This review and trending process for assessing units with recent reassessments was first implemented for the 1996 market value survey and, for a substantial portion of the State, it has eliminated the costly sampling of rolls and appraisal of parcels that had been undertaken in prior surveys.

For the remaining approximately 44 percent of assessing units that did not have recent reassessments, samples of sales and appraisals, and computer-assisted mass appraisal (CAMA) models, were used to determine the local average level of assessment, and variation around this average. Where reliable residential sales data reflecting the appropriate time frame were available, such sales were used to replace or augment individual parcel appraisals. CAMA techniques were employed where insufficient residential sales were available but local property inventories were satisfactory for statistical modeling purposes. For the non-residential property classes -- generally characterized by greater heterogeneity and complexity -- individual sampled parcels were appraised if the property class represented a significant component of the total value on the roll.

Uniformity of assessments on the sampled rolls was measured primarily through a statistic known as the Coefficient of

Dispersion (COD). This statistic measures the extent of assessment "error" observed among the assessment ratios (assessed value divided by market value) of the sample parcels. Ideally, all ratios within an assessing unit (or, for New York City and Nassau County, within a property class) should be the same, indicating perfectly uniform assessments. However, unavoidable imperfections in valuation and estimation error require that some minimum level of variation be deemed acceptable. The amount of variation that is acceptable is a function of the type of property and the amount of market activity in a given community, with the most rural areas generally capable of attaining assessments that are less uniform than those attainable in urbanized areas, due to greater variability among properties and sparse market data for some or all property types.

Among the sampled assessing units, approximately 40 percent had COD estimates for the entire assessment roll that satisfied State guidelines, which in turn are based on standards established by the International Association of Assessing Officers (IAAO). In terms of residential property, where allowable COD levels are more stringent, 21 percent met the guidelines.

Introduction

Distributional equity in real property taxation requires that properties of the same value be treated alike in terms of their assessments. New York State law (Section 305 of the Real Property Tax Law) stipulates that assessing jurisdictions must assess properties at a uniform percentage of value, and State courts have held that "value" means "market value." New York's two "special assessing units," New York City and Nassau County, must assess at a uniform percentage of market value within each of four specified property classes. This means that all parcels on the assessment roll (or, for special assessing units, within each class) should have the same, or at least very similar, assessment ratios (assessed value divided by market value). Each assessing unit has the right to choose the percentage of value to be used as an assessment standard.

The New York State Department of Taxation and Finance has statutory responsibility for regularly monitoring the equity of assessments. An analysis of assessment uniformity is carried out each time the Department's staff completes a market value survey. The present report documents findings from the 2012 market value survey.

Included herein is information for the State's 983 non-village assessing units, which consist of 2 counties, 61 cities and 920 towns.

¹This analysis is required by Section 1200 of the Real Property Tax Law.

2012 Market Value Survey Data and Estimation Methodology For the 2012 market value survey, the level of assessment uniformity for each assessing unit was estimated using one of four possible approaches, as outlined below:

- Sales Ratio Study This approach involves a systematic comparison of assessed values to sales prices for properties that have sold. It is used if there is a sufficient sample of sales to provide a reliable estimate of the ratio of assessed value to sales price. The sales prices may be time-adjusted to a common valuation date in order to establish value and assessment ratio as of that date. It is used for residential property only, and supplemented by appraisals for other property types.
- 2. Computer Assisted Mass Appraisal Ratio Study
 (CAMA) CAMA involves a systematic comparison
 of assessed values to market values generated by a
 statistical model. The model uses a multiple regression
 equation to predict the market value of residential
 parcels based on sales data and the physical inventory
 characteristics of the parcels. The CAMA approach is
 particularly useful in municipalities with few sales but
 good parcel inventory data. It is used for residential
 property only, and is supplemented by appraisals for
 other property types.
- 3. Stratified Sample of Parcels, Using Appraisals and/or Sales A stratified sample was used where suitable data were available and the sales ratio and/or CAMA approaches were determined to be inappropriate. Direct use of time-adjusted sales in ratio determination was limited to residential property, and sample parcels were weighted based on the incidence of each type on the assessment roll.
- 4. Review and Verification of a Recent Reassessment -The review and verification process was used in assessing units having conducted recent reassessments. It involves an audit—type analysis of the reassessment process and its results to verify that assessments adequately reflect current market conditions. As part of the review, an extensive audit document is completed (see example in Appendix A) in which the data and analytical processes used to determine the assessments are examined in relation to acceptable professional standards of practice.

Approaches 1 through 3 result in independent computations of the local level of assessment and the assessing units in question are referred to in this report as the "sampled assessing units." Classes of property comprising a very minor portion of the value on the assessment roll may not have been independently valued. The full value of these classes was estimated by applying the overall ratio of the sampled classes. In some cases, appraisals from a prior, recent market value survey may have been reused in the 2012 market value survey.

As mentioned above, assessing units having completed recent reassessments were not sampled, primarily to focus available resources on those with older assessment rolls. These units were handled through the fourth approach, "Review and Verification of a Recent Reassessment," and are referred to as "non-sampled assessing units." A recent reassessment means that the assessing unit has an equitable assessment roll, unless significant errors have been made in the reassessment process, in which case the roll would not have been accepted for review and verification in the survey. Therefore, in the statistical tabulations presented in this report concerning assessment equity, assessing units wherein the review of reassessment procedure was used and the reassessment was deemed acceptable have been counted as meeting equity standards.

It should be understood, however, that the designation of assessing units as having adequate equity does not necessarily imply that all properties in them are accurately assessed. Factors such as uniqueness of certain properties, rapidly changing neighborhood conditions and/or dynamic market segments in certain time periods, and other such factors, will necessarily mean that there will be inevitable imperfections on the roll, as assessment is not an exact science.

Statistical Measurement of Assessment Uniformity

The primary means of measuring assessment uniformity is a statistic known as the Coefficient of Dispersion (COD). The COD measures the extent to which the assessment ratios from a given roll exhibit dispersion around a midpoint. It is generally accepted that the median assessment ratio best serves as the midpoint or central tendency measure from which the average level of dispersion should be calculated.

Assessing units with good assessing practices have low CODs, showing little deviation of individual assessment ratios from the median ratio. For example, if the median ratio for the parcels

sampled in a given assessing unit is 50 percent, a house with a market value of \$100,000 should be assessed at \$50,000, a commercial property valued at \$400,000 should be assessed at \$200,000, and a \$2,000,000 industrial parcel should be assessed at \$1,000,000. If all other sampled parcels were similarly assessed at 50 percent of market value, the median ratio would also be 50 percent and the average deviation, as measured by the COD, would be zero. Conversely, an assessing unit with little assessment uniformity would have widely varying assessment ratios among the sampled parcels, resulting in high dispersion around the median ratio and, therefore, a high COD. Widely varying ratios result in unequal tax bills for properties of equal value.

Examples 1 and 2 show two hypothetical assessing units, each attempting to assess properties at 80 percent of market value. In Example 1, the assessed values range from 52 percent to 120 percent of market value, indicating a relatively high level of dispersion and poor assessment practices. Assessments such as these would result in an inequitable distribution of local taxes between property owners.

Example 1. Coefficient of Dispersion of 30 Percent: Low Uniformity

Parcel #	Assessed Value	Market Value	AV/MV Ratio	Absolute Deviation from Median
1. 2. Median 3. 4. 5.	\$120,000 110,000 80,000 58,000 52,000	\$100,000 100,000 100,000 100,000 100,000	1.20 1.10 .80 .58 .52	.40 .30 .00 .22 .28
			Total Deviat	ion 1.20
-	Total Deviation =	$\frac{1.20}{5}$ = .24 av	erage deviation from me	dian
	COD =	g. Deviation = -	.24 = 30 percer	nt

Example 2 shows a hypothetical case where assessments are more uniform. The assessment ratios range from 64 percent to 92 percent, and are closer to the target ratio of 80 percent, showing substantially less dispersion than is evident in Example 1. While some dispersion is indeed present, it is significantly lower than in the previous example and within an acceptable range when factors such as measurement error and valuation uncertainty are taken into account.

Example 2. Coefficient of Dispersion of 10 Percent: Acceptable Uniformity

Parcel #	Assessed Value	Market Value	AV/MV Ratio	Absolute Deviation from Median
1. 2. Median 3. 4. 5.	\$92,000 88,000 80,000 76,000 64,000	\$100,000 100,000 100,000 100,000 100,000	.92 .88 .80 .76 .64	.12 .08 .00 .04 .16
			Total Dev	iation .40
-	Total Deviation =	$\frac{.40}{5}$ = .08 ave	rage deviation from media	n
	COD =	g. Deviation = -	.80 = 10 perce	ent

A second statistical measure of assessment uniformity, called the Price-Related Differential (PRD)² is also used in the current report for assessing units with no recent reassessment activity. The PRD is used to determine if there is a bias on an assessment roll toward systematic over-assessment of either high- or low-value properties in comparison to the average property. In computing the PRD, the simple mean of the assessment ratios is divided by the value-weighted mean ratio. If no bias exists, the two ratios should be close to each other, and the PRD should be near 1.00. This is referred to as "neutral" assessment practice, i.e., no price-related bias.

²This statistic is sometimes referred to as the Index of Regressivity.

However, if the simple mean ratio is considerably lower than the value-weighted mean, a low PRD results (less than 1.00). In this case, there is said to be a bias toward "progressivity," that is, higher-value properties are being over-assessed and lower-value properties are being under-assessed. In the opposite situation, where the PRD is high (greater than 1.00), "regressive" assessing is evident. In other words, lower-value properties are being relatively over-assessed and higher-value properties are being relatively under-assessed. The International Association of Assessing Officers (IAAO) has established a range for the PRD which denotes uniform practices, i.e., neutral assessing: the PRD must fall in the range 0.98 to 1.03 to be considered acceptable.

Coefficient of Dispersion Standards

Upon the completion of a market value survey, two coefficients of dispersion are calculated for the assessing units with no recent reassessment activity, one for residential property alone and one for all property classes combined. To evaluate the CODs calculated in this process, they must be compared to accepted guidelines for assessment uniformity. The International Association of Assessing Officers, in its publication entitled Standard on Ratio Studies (January 2010), has recognized that the ability of an assessing unit to attain uniformity is affected by several factors, such as the types of property it contains, community size, population density, the degree of diversity of properties, market activity levels, and the relative ages of structures. The IAAO recommends a range of acceptable COD values, based on these categories and neighborhood characteristics, as well as the increased difficulty experienced in assessing classes of property other than residential. IAAO standards are summarized in Table 1.

Table 1. Ratio Study Uniformity Standards Indicating Acceptable General Quality, IAAO*

Type of property - General	Type of property - Specific	COD Range**	
Single-family residential (including residential	Newer or more homogenous areas	5.0 to 10.0	
Single-family residential	Older or more heterogeneous areas	5.0 to 15.0	
Other residential	Rural, seasonal, recreational, manufactured housing, 2-4 unit	5.0 to 20.0	
Income-producing properties	Larger areas represented by large	5.0 to 15.0	
Income-producing properties	Smaller areas represented by	5.0 to 20.0	
Vacant land		5.0 to 25.0	
Other real and personal property		Varies with local conditions	

^{*}These types of property are provided for general guidance only and may not represent jurisdictional requirements.

^{**} CODs lower than 5.0 may indicate sales chasing or non-representative samples.

In its work with various types of assessing units, the Department's staff has also found that the more rural areas, where there are relatively few sales and properties are more heterogeneous, pose greater difficult in establishing accurate assessments and market values. Thus, in measuring assessment uniformity, staff has taken the view that somewhat higher COD levels would be acceptable in areas with rural characteristics as contrasted with urban and suburban areas. The guidelines established are summarized in Table 2 and were applied in determining the number of assessing units achieving equity for purposes of this report.

Table 2. Department Guidelines for Assessment Uniformity

Population Density (persons/sq. mile)	Coefficient of Dispersion, All Property
100 or less	≤ 20
101 to 400	≤17
401 or more	<15

Coefficient of Dispersion Results

For the 2012 market survey, the median residential COD among the sampled assessing units was 17.73, and the median for all property classes combined was 19.85.³ In other words, half the sampled assessing units achieved greater uniformity than indicated by these median values, and half achieved less. The range in the all-property COD was 6.05 to 124.90. For the residential COD, the range among assessing units was 5.13 to 60.32.

The COD results presented herein are point estimates. If the estimation were replicated using an alternative data set, it is likely that somewhat different figures would be obtained due to sampling error. Gloudemans, an expert in the field, has proposed a confidence interval approach to recognize the problem of sampling error. His approach results in a range within which the COD estimate will fall with a known probability. However, the approach does not obviate the need for making point estimates of the COD.⁴

³The special assessing units of New York City and Nassau County are excluded in calculating the median COD because they use a classified assessing system.

⁴See Robert J. Gloudemans, "Confidence Intervals for the Coefficient of Dispersion: Limitations and Solutions," Assessment Journal, Nov./Dec. 2001.

Table 3 summarizes the 2012 COD information according to type of assessing unit, as measured by population density, and the COD guidelines shown in Table 2. A total of 40 percent of the sampled assessing units had 2012 CODs that reflected uniform assessing practices for the entire roll. In the case of residential property only, 21 percent of the sampled units had uniform rolls.

Table 3. Summary of COD Values for Sampled, Assessing Units, by Degree of Urbanization (2012 Market Value Survey)

Population Density	No. of	Uniform COL) Guideline	Percent of Assessing Units Achieving Uniform Level	
(Per Sq. Mi.)	Assessing Units	Residential	All Property	Residential	All Property
≤100	228	15	20	18%	34%
>100 - ≤400	106	12	17	26%	47%
>400	97	10	15	24%	45%
TOTAL	431	-	-	21%	40%

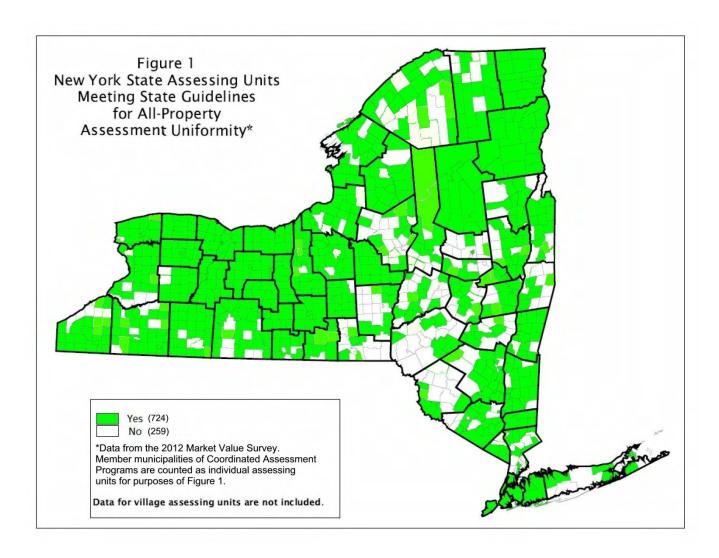

Note: Data for the individual municipalities within a Coordinated Assessment Program (CAP) are reported.

Table 4 shows the combined results for sampled and non-sampled Assessing units. When the non-sampled units – those for which a recent reassessment program was reviewed and verified – are combined with sampled units achieving satisfactory uniformity, a total of 724 (73.7%) of the state's assessing units had uniform assessment rolls. This represents an increase of one assessing unit over the number found to be equitable in the 2011 survey analysis.

Table 4. Assessment Uniformity, Sampled and Non-Sampled Assessing Units* (2012 Market Value Survey)

	T-4-1	Number with Uniformity		
	Total	Residential	All Property	
Sampled	431	91	172	
Non-Sampled	552	552	552	
Total	983	643 (65.4%)	724 (73.7%)	
*Data for the individual municipalities within a Coordinated Assessment Program (CAP) are reported.				

The geographical distribution of equitable assessing is shown in Figure 1. It can be observed that, in many parts of New York, all or nearly all the municipalities in a county have uniform rolls. On the other hand, clusters of rural assessing units with inequitable rolls are to be found in several areas, including the Northern Catskills, Southern Tier, Adirondacks and Southwestern New York. Some of the densely populated units in the Lower Hudson Valley and Long Island areas also have not achieved equitable rolls.

Another view of the equity of assessment rolls can be obtained from analysis of the <u>level of assessment</u> reflected on the roll, as contrasted with the <u>degree of uniformity</u>. Table 5 shows the distribution of 2012 equalization rates, which reflect the average percentage of market value used in assessing. The data indicate that over 69 percent of all assessing units now have assessments that are at least 75 percent of current market value. Although there are some assessing units with assessments that are well below market value but which are still uniform and equitable, experience has demonstrated that current market assessments are strongly correlated with equity, and the level of assessment findings thus support the Table 4 data on assessment uniformity.

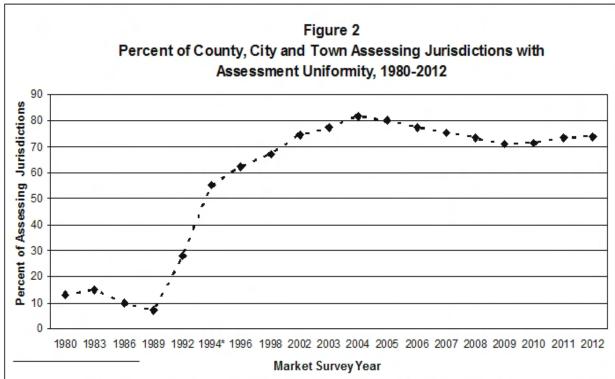

The 92 assessing units having a level of assessment of 25% or less probably have decades-old rolls, i.e., no general reassessment program has likely been conducted in a great many years. The additional 49 having a level of assessment in the 25% to 50% range are also very outdated, even in areas of the State where real estate markets experienced rapid appreciation during certain periods.

Table 5. Level of Assessment, as Measured by 2012 State Equalization Rate

Level of Assessment	Number of Assessing Units*	
0.00 - 10.00	57	(5.8%)
10.01 - 25.00	35	(3.6%)
25.01 - 50.00	49	(5.0%)
50.01 - 75.00	159	(16.2%)
75.01 - 100.00	656	(66.9%)
Greater than 100.00	25	(2.5%)
Total	981	(100%)

*Data for the individual municipalities within a Coordinated Assessment Program (CAP) are reported. Data for special assessing units of Nassau County and New York City are excluded.

Figure 2 shows the trend in assessment uniformity among New York assessing units since 1980. In the 1980s, only about 10 percent of all assessing units had acceptable uniformity. Dramatic improvement occurred in the early 1990s however, and by 2004, over 80 percent of all assessing units were assessing uniformly. There were modest declines thereafter, in a context of turbulent real estate market conditions in some areas, which persist to the present day. It is believed that real estate market volatility is the primary reason for the noticeable lack of progress in achievement of greater uniformity over the past decade.

^{*} In measuring assessment equity for 1994 and subsequent survey years, acceptable levels of the coefficient of dispersion (COD) statistic were increased for the more rural assessing units. Recent reassessment programs that were reviewed and verified for the 1996 and subsequent surveys were deemed uniform.

Price-Related Differential Results

As indicated earlier, another important summary statistic for assessment performance is the price-related differential (PRD). The PRD is calculated by dividing the simple mean assessment ratio by the weighted mean ratio, where the weighted mean is the sum of assessed values divided by the sum of sales prices and/or appraised values. The simple mean counts the ratio of each property equally, regardless of the property's value, whereas the weighted mean counts each ratio differently, weighting ratios of higher-value properties more heavily, in proportion to their dollar value. If no assessment bias exists, the two mean ratios should be equal, producing an index of 1.00. Where there is evidence of a bias in favor of under-assessing the higher-value properties relative to the lower-value ones, the simple mean ratio will be higher than the value-weighted mean ratio, producing an index greater than 1.00 (regressivity). The reverse will be true in cases of over-assessment of high-value properties relative to those of low-value (progressivity). IAAO suggests that the PRD have a value between .98 and 1.03 for neutral assessing.

Table 6 summarizes the extent of value-related equity as measured by the PRD for sampled assessing units. About 43 percent of the sampled assessing units assessed residential property in a neutral manner, i.e., they generally did not tend to favor either high- or low-value properties. However, 56 percent tended to over-assess low-value homes relative to high-value homes, while only two units tended to do the reverse. These results are similar to those found in the prior market value survey.

Table 6. Value-Related Bias in Assessing, Sample Assessing Units, 2012 Market Value Survey

	Residential Class		All Property Classes	
Price-Related Differential	Number of Assessing Units	Percent	Number of Assessing Units	Percent
Progressive	2	1%	84	19%
Neutral	186	43%	167	39%
Regressive	243	56%	180	42%
TOTAL	431	100%	431	100%
Note: Data for the inc	lividual municipalities within			

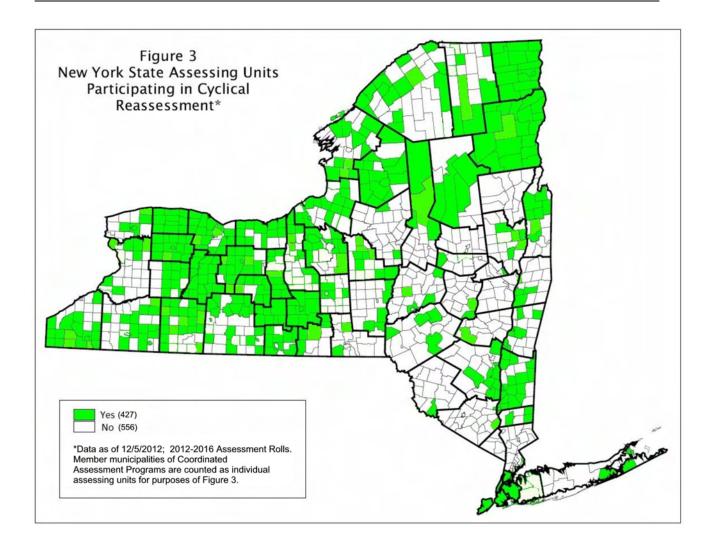

Page 12

When all property classes are combined, the situation changes significantly. Table 6 shows that 19 percent of the sampled assessing units use assessing practices that are biased toward over-assessment of higher-value properties, indicating over-assessment of some non-residential classes (generally industrial, commercial and utility property). About 42 percent demonstrate the opposite behavior, regressive assessing, meaning that they tend to overvalue the lower-priced properties (generally vacant land or low-value residential parcels). The remaining 39 percent of the assessing units assess in a neutral manner with respect to value when all property classes are considered together.

Recent Reassessment Activity Subsequent to the 2012 Market Survey

Approximately 7 percent (30) of the 431 assessing units for which CODs and PRDs were calculated are conducting or plan to conduct a reassessment on a roll subsequent to the one that was utilized in the 2012 survey. For these assessing units, the COD and PRD estimates contained in this report are a measure of past assessment equity only; the level of uniformity on the newer roll may well be significantly improved from the level on the roll evaluated. Of the 552 assessing units for which recent reassessment projects were reviewed for the 2012 market value survey, 439 have scheduled a subsequent reassessment project. With the recent inception of the Cyclical Reassessment Aid Program, and its requirement to complete a reappraisal at least once in every four years, these subsequent reassessments will be performed on a roll completed between 2013 and 2016, depending on the schedule of the municipality's planned participation. Thus, approximately 80 percent of those that have already taken steps to maintain equitable assessing practices are projecting that they will reassess again in the next three to four years.

Figure 3 indicates the number of municipalities that have submitted plans for the Cyclical Reassessment Aid Program. As of December 5, 2012, some 427 assessing units are committed to updating their assessment rolls on a regular basis, thus ensuring that equity will be maintained as market conditions change. It should be noted that the Cyclical Reassessment Program is still in a period of transition and, apart from the requirement for a reappraisal at least once every four years, offers municipalities options in terms of the frequency of their reassessments. One option is to reassess annually, but the number who do so cannot be accurately measured at this time.

Conclusions and Recommendations

Achievement of assessment equity in New York improved dramatically over the past thirty years, reached a peak in 2004 and, since then, has hovered around 70 to 80 percent of assessing units. Following the large gains in earlier years, there seems to have been a moderate decline in the second half of the past decade, and more than one quarter of assessing units currently have very outdated assessments. It appears that existing aid programs for quality assessment administration are no longer attracting significant numbers of new participants. Thus, it may be worthwhile for policymakers to consider additional tools to bring about greater assessment equity. Other states employ a number of such tools, and virtually all states have more requirements directed at maintenance of assessment uniformity than New York has.

Standard of Assessment

All states other than New York, New Jersey, and Pennsylvania require that a common level of assessment (most frequently, 100 percent of current market value) be applied in all assessing jurisdictions). This approach has many advantages, including, equitable tax treatment of like properties, greater taxpayer understanding of the basis of the tax, and both fair and cost-effective apportionment of taxes and state aid among local governments. It is also consistent with recommendations of the IAAO concerning the most appropriate state policies with respect to assessment standards.

Reassessment Cycle

In recognition of the fact that real estate markets are constantly changing, many states require that assessments be updated periodically. While annual updating is the ideal, actual practice usually involves cycles that generally range from two to six years, in recognition of the time that is generally needed to accumulate sufficient market data (especially in small, rural assessing units), the amount of work required, including data verification, valuation, outreach to property owners, and assessment appeals, and the cost of the entire process. While New York's aid incentive program for reassessment now provides for a four-year reassessment cycle, it must be understood that the program is not mandatory.

Direct Equalization

States using this policy tool directly change assessments on the rolls prepared by local governments, in contrast to the indirect equalization used in states such as New York, where the portion of a county or school tax levy to be borne by a particular municipality is adjusted in recognition of that municipality's overall level of assessment. The main advantage of direct equalization is that it changes the assessment, so that property owners can then compare their assessments to local market prices. A limitation, however, is that the state-level adjustments may well be quite crude factors that are applied to an entire property class or assessment jurisdiction, especially when adjustments must be made for many assessing units.

Withholding of State Payments

Rather than attempt to make rough adjustments to assessments in order to bring them to the correct market level, many states instead use monetary sanctions. These generally involve the withholding of monies that local governments would ordinarily receive from the state on an annual basis, such as state aid payments, a local share of certain state taxes, or fees that

are collected by the state and sent to local governments, in whole or in part. The payments are restored only when the assessments in question are brought up to state standards.

Ordering a Reassessment

Some states simply direct a local government with faulty assessments to conduct a reassessment and, if the locality in question fails to comply with the directive, the state may hire a contractor to do the work and charge the local government for the cost of the project. Massachusetts is a nearby state where such action is the final remedy for outdated or inequitable assessments.

Assessing Unit's Stated Uniform Per	centage of Value:		
Reviewer:	Review Comple	etion Date:	
Meviewei.	Venien Combie	stion Date.	

1) GENERAL DESCRIPTION OF REASSESSMENT

RPTL Section 102 defines a reassessment as "the systematic analysis of the assessments of all locally assessed properties, valued as of the valuation date of the assessment roll containing those assessments, to attain compliance with the standard of assessment set forth in subdivision two of Section 305. RPTL". Is there intent on the part of this assessing unit to comply with the requirements for Aid pursuant to RPTL Section 1573 (6) (2) (a)? [Y/N] 2 Enter the assessment roll year of the most recent previous assessing unitwide reappraisal. Enter NA if previous effort was more than ten years ago. 3 Is this year's reassessment effort a complete assessing unit-wide reappraisal? [Y/N] 4 Is this year's reassessment effort being assisted by a vendor? [Y/N] 5 What was the Equalization Rate for the prior year's assessment roll? 6 Has the municipality adopted Article 19 (Homestead) in conjunction with this reassessment or is Article 19 already in effect?

2) DOCUMENTATION FOR FINDINGS FOR SYSTEMATIC ANALYSIS

a. Acquisition and Maintenance of Parcel Inventory Data

Major Types A, B, and C

1	Data Items: Does the assessing unit's parcel inventory database contain all the data items specified in 9NYCRR Parts 190? [Y/N]					
	If the assessing unit is using RPS V4, answer Y and proceed to Question #2. Otherwise, complete the Checklist in Appendix A and continue to 1. a. below.					
	a. If N , what data item(s) are missing?					
	 b. If N, in the reviewer's opinion, will these missing data items adversely affect the assessing unit's capacity to conduct systematic analysis? If Y to this question, provide an explanation below. 					
2	Enter the assessment roll year of the last municipal-wide data collection or verification project.					
3	Enter the assessment roll year of the last municipal-wide issuance of inventory data mailers or equivalent.

Regional Manager's Determinations

Based on the findings and recommendations on the preceding pages, I have made the following determinations:	Y/N
Does this assessing unit meet the uniformity criteria for State Aid purposes?	
Has the assessing unit substantially complied with statutes and rules as outlined in 9NYCRR 201-2?	

Regional Manager's Summary of Findings and Recom	mendations:				
It is determined that the City/Town of ,	County;				
gualifies for State Aid for its <u>20XX</u> assessment roll	based upon the findings of staff and for the				
reasons discussed in my conclusion included here					
, , , , , , , , , , , , , , , , , , , ,					
does <i>not</i> qualify for State aid for its <u>20XX</u> assessn					
for the reasons discussed in my conclusions include	ded herein.

Appendix B — Measuring Assessment Uniformity from Market Survey data: Weighted Coefficient of Dispersion

APPENDIX B

MEASURING ASSESSMENT UNIFORMITY FROM MARKET SURVEY DATA: WEIGHTED COEFFICIENT OF DISPERSION

1. Computing the Coefficient of Dispersion

The coefficients of dispersion (CODs) contained in this report are calculated from the estimates of market value (sales, appraisals, and Computer Assisted Mass Appraisal (CAMA) estimates) derived in the New York State Board of Real Property Tax Services' 2012 market value survey. "Weighted" CODs for the entire assessment roll are calculated when appraisals and/or sales are available and are used to reflect the composition of each assessment roll appropriately, as rolls may be stratified by property type and value category for survey purposes. In contrast, CODs calculated through CAMA need not be weighted as they use data for all the parcels for which values are being predicted.

The general formula for a coefficient of dispersion around the median assessment ratio is:

(1)
$$COD = \frac{100}{R_m} \left(\begin{array}{c} N \\ \Sigma \mid R_i - R_m \mid \\ \frac{1}{N} \end{array} \right)$$

where:

COD = coefficient of dispersion, i.e., the average percent of dispersion around the median assessment ratio:

 R_m = median assessment ratio;

R_i = observed assessment ratio for each parcel;

N = number of properties sampled.

This general formula is usually applied in estimating the COD from non-stratified sales data, where the true representativeness of each sale is unknown. Where a sales ratio analysis was used directly in the survey (residential property only), the formula above describes the residential COD calculation accurately. Where a stratified sample was used and the

representativeness of each sampled parcel is known, the formula can be modified by weighting each of the observed assessment ratios as follows:

Let i = the sampled parcel, j = the stratum, and R_{ij} = the assessment ratio of the i^{th} parcel in the j^{th} stratum.

Let $w_j = p_j / s_j$, where:

p_j = the total number of parcels on the assessment roll in the jth stratum;

 s_j = the number of sampled j^{th} stratum.

Let W = the total number of parcels on the roll divided by the total number sampled (i.e., the reciprocal of the overall sampling ratio).

The weight (w_i) is calculated for each stratum, and is identical for all sampled parcels within it. For example, in a municipality where there are 600 residential parcels in the assessed value range of \$40,000 to \$80,000, and six of them are selected in a random sample, then each of the six sample ratios would have a weight of 100 because it is assumed to represent 100 of the parcels in that range (stratum).

Since i signifies the sampled parcel and j the stratum it was selected from, the assessment ratio for a given observation will thus be Rij. As in the case of formula (1) above, we must calculate the absolute difference between Rij and Rm. Then, these differences are adjusted to reflect the composition of the entire roll rather than the sample by applying to each the ratio wj/w. For all observations within each of the i strata, the formula for the weighted coefficient of dispersion around the median thus becomes:

(2)
$$COD_w = \frac{100}{R_m} \begin{bmatrix} i & j & w_j \\ \Sigma & \Sigma & \frac{}{-} & | & R_{ij} - R_m | \\ \frac{1}{N} & \frac{1}{N} & \frac{}{N} \end{bmatrix}$$

The procedure for calculating the weighted coefficient for each assessing unit entails the following steps.

1. Calculate the assessment ratio (R_{ii}) for each sample parcel by dividing the assessed value by the estimated market value.

- 2. Array the assessment ratios from lowest to highest within each assessing unit.
- 3. Calculate the weight (w_i) for each stratum and W, representing the total number of parcels on the roll divided by the size of the sample.
- 4. Normalize the weight of each sampled parcel by dividing by (W).
- 5. Select the median assessment ratio (R_m) from the weighted list (length of list equals the total number of parcels sampled.)
- 6. Apply equation (2) above.

It is important to note that the median assessment ratio as used in equation (2) will not necessarily be the same as the median of the sampled ratios, i.e., as used in equation (1). The former median, from the "weighted" list of appraisals, reflects the weighting applied to achieve equal representativeness in the population.

For cases where the stratification process is embedded even further, such as multiple school district portions within an assessing unit, the calculations embodied in these equations entail additional subscripts. However, the general form of the equation remains the same. Once again, the purpose of weighting is to correct, to some degree, the deficiencies of the sampling procedures from the standpoint of measuring uniformity, i.e., to construct a measure built upon equally-likely selection of each parcel from an assessment roll.

In instances where CAMA model estimates were used in lieu of regular appraisals (residential property only), the COD calculation procedure was modified as follows: (1) a residential COD was computed for the modeled residential parcels, according to the formula in equation (1) above; (2) a non-residential COD was computed for the remaining parcels using the formula given in equation (2) above; and (3) to compute an all-property weighted COD, these two COD estimates were combined through weighting them according to relative parcel numbers.

II. Computing the Price-Related Differential

The price-related differential (PRD) is used to determine if there is a price-related bias in a municipality's assessing practices. It compares the simple mean of the assessment ratios to the price-weighted mean ratio. If no bias exists, the two figures will be virtually equal and the PRD would be close to one (1.0), indicating assessment neutrality. If a municipality tends to over-assess higher valued properties, the price-weighted mean will be higher than the simple mean and an index of less than 1.0 will result (indicating progressivity). The opposite occurs

when higher-valued properties are consistently under-assessed. In this case, the price-weighted mean will be lower than the simple mean and the result will be an index which is greater than 1.0, indicating regressivity.

Example of Price-Related Differential Values

	Regressive Greater than 1.03	Neutral 0.98 to 1.03	Progressive Less than 0.98
Ratios:	70	70	70
a. Simple Mean b. Price-weighted Mean	.70 .58	.70 .68	.70 .85
S. Thee Weighted Mean	.00	.00	.00
Price-Related Differential (a / b)	1.21	1.03	0.82

The formula for the price-related differential uses the same weighting process previously described in relation to the coefficient of dispersion:

where:

N = the total number of sampled properties;

i = the sampled parcel;

j = the stratum;

w_j = the weight of every sampled parcel drawn from the jth stratum (see previous discussion of sample weighting in relation to COD);

w = the total number of parcels in a stratum divided by the total number sampled in that stratum (see previous discussions of sample weighting in relation to COD; R_{ij} = ratio of assessed value to estimated market value (appraisal or sale) (one for each sampled property in each stratum);

 ASV_{ij} = assessed value of the "ith" sampled property in the jth stratum; and

 EMV_{ij} = estimated market value of the "ith" sampled property in the jth stratum.
